ABSTRACT

Crochemore and Rytter introduced in 1995 a structural lemma on three squares starting at the same position. This influential lemma has been used by many researchers in the field of periodicities in strings. In particular, Fraenkel and Simpson used it in 1998 to obtain a universal upper bound for the maximum number of distinct squares occurring in a string. We present a generalization of Crochemore and Rytter's lemma by exploiting the combinatorics of two squares starting at the same position.

© 2015 Published by Elsevier B.V.

1. Introduction

Crochemore and Rytter [3] introduced in 1995 the following Lemma 1.

Lemma 1. (See [3].) *Let $u^2 \neq v^2$ be proper prefixes of w^2 and let u , v , and w be primitive, then $|u| + |v| \leq |w|$.*

Lemma 1 has been used by many researchers including Kolpakov and Kucherov [9], Stoye and Gusfield [12], Fan, Puglisi, Smyth, and Turpin [5], Simpson [11]. Lemma 1 was essential for the 1998 result by Fraenkel and Simpson [7] giving a universal upper bound of $2n$ for the number of distinct squares in a string of length n . Note that for the problem of distinct squares, every type of square is only counted once, i.e. the types, rather than the occurrences, are counted. For illustration, $aabaab$ contains the following three underlined squares \underline{aabaab} , \underline{aabaab} and \underline{aabaab} while the number of distinct squares is 2: aa and $aabaab$. Ilie [8] provided in 2005 an alternate proof of the main theorem of [7] not directly using Lemma 1. Noticing that the proof of Lemma 1 by Crochemore and Rytter only requires the primitiveness of the shortest square, Fraenkel and Simpson [7] proposed the following strengthening referred to as Three-prefix-square Lemma in [2] where additional context and references can be found.

Lemma 2. (See [7].) *Let $u^2 \neq v^2$ be proper prefixes of w^2 and let the shorter of the two strings u and v be primitive, then $|u| + |v| \leq |w|$.*

Fraenkel and Simpson illustrated the necessity of the primitiveness for the shortest square with the following example: $u = a^2$, $v = a^4$, and $w = a^5$. We present a further strengthening based on the recently investigated structural properties of two squares starting at the same position, see [1,4]. The proof of Lemma 3 is given in Section 3 not to impede the clarity of the exposition.

Lemma 3. Let $u^2 \neq v^2$ be proper prefixes of w^2 , then $|u|+|v| \leq |w|$ unless u, v , and w have the same primitive root.

Note that Lemma 3 implies that if $|u|+|v| > |w|$, then u, v , and w have the same primitive root r and thus $u = r^i, v = r^j$, and $w = r^k$ where $1 \leq i < j < k$ and $k < i+j$. In other words, the type of the example given by Fraenkel and Simpson is essentially unique. The following Corollary 4 illustrates that Lemma 3 is a generalization of Lemma 2.

Corollary 4. Let $u^2 \neq v^2$ be proper prefixes of w^2 and at least one of u, v or w be primitive, then $|u|+|v| \leq |w|$.

Proof. Let us assume by the way of contradiction that $|u|+|v| > |w|$. For the sake of simplicity assume that $|u| < |v|$. Then by Lemma 3, u, v , and w have the same primitive root r . Thus, $u = r^i$ for some $i \geq 1, v = r^j$ for some $j > i \geq 1$ as $|v| > |u|$, and $w = r^k$ for some $k > j \geq 2$ – and therefore $k \geq j+1$ – as $|v| < |w|$, and $k < i+j$ as $|w| < |u|+|v|$. Therefore, neither v nor w is primitive, and so u must be primitive forcing $i = 1$. It follows that $k < i+j = 1+j$ but also $k \geq j+1$, a contradiction. \square

2. Preliminaries and notations

For a string x , we use the indexing from 1, i.e. $x[1]$ refers to the first symbol of $x, x[2]$ the second symbol of x etc. The string $x = x[1 \dots n]$ is a sequence of n symbols and the length, also called size, of a string x is denoted by $|x|$. The same range notation is used for substring, also called factor, i.e. $x[i \dots j]$ refers to the string consisting of $x[i]x[i+1] \dots x[j]$. The string of length 0 is called the empty string. Given a string $x = x[1 \dots n]$ and $1 \leq i \leq n$, the substring $x[1 \dots i]$, respectively $x[i \dots n]$, is called a prefix, respectively suffix, of x and we speak of a proper prefix, respectively proper suffix, if $i \neq n$, respectively $i \neq 1$. For an integer $n \geq 2$, the n th power of a string x , denoted x^n , is a concatenation of n copies of x . In particular, x^2 is referred to as a square. A string x is primitive if it is not a power of at least 2 of some non-empty string. For a string x , the unique shortest primitive u so that $x = u^k$ for some integer $k \geq 1$ is called the primitive root of x . For two substrings y and z of x , $lcs(y, z)$ refers to the length of the longest common suffix of y and z , while $lcp(y, z)$ refers to the length of the longest common prefix of y and z .

A right shift by one position of a substring $x[i \dots j]$ is the substring $x[i+1 \dots j+1]$. The shift is referred to as cyclic, if $x[i] = x[j+1]$. In such case, we say that the substring $x[i \dots j]$ can be cyclically shifted one position to the right or right cyclically shifted by one position. A substring $x[i \dots j]$ can be cyclically shifted right by k positions if each of the substrings $x[i \dots j], \dots, x[i+k-1 \dots j+k-1]$ can be cyclically shifted by one position to the right. For instance, for $x[1 \dots 5] = abaaa$, the substring $x[1 \dots 2] = ab$ can be cyclically shifted right by 1 position, but not by 2 positions; similarly $x[1 \dots 3] = aba$ can be cyclically shifted right by 1 position, but not by 2 positions; if $x[1 \dots 5] = aabaa$, then $x[1 \dots 3] = aab$ can be cyclically shifted by 2 positions to the right while $x[1 \dots 2]$ cannot be cyclically shifted by 3 positions.

Similarly, a left shift by one position of a substring $x[i \dots j]$ is the substring $x[i-1 \dots j-1]$. The shift is referred to as cyclic, if $x[i-1] = x[j]$. In such case we say that the substring $x[i \dots j]$ can be cyclically shifted one position to the left or left cyclically shifted by one position. A substring $x[i \dots j]$ can be cyclically shifted left by k positions if each of the substrings $x[i \dots j], \dots, x[i-k+1 \dots j-k+1]$ can be cyclically shifted by one position to the left. Strings x and y are conjugates if $x = uv$ for some strings u and v and $y = vu$. Equivalently, x is a rotation of y or that y is a rotation of x . If either $|u| = 0$ or $|v| = 0$, we speak of a trivial rotation. Note that a left cyclic shift of $x[i \dots j]$ is a rotation of $x[i \dots j]$, i.e. they are conjugates, similarly for a right cyclic shift.

The notion of double squares and their factorization can be traced to Lam [10], and was further investigated and generalized by Deza, Franek, and Thierry [4] and by Bai, Franek, and Smyth [1].

Definition. A double square (u, v) consists of a square u^2 that is a proper prefix of a square v^2 . A double square (u, v) is balanced if u and v are proportional; that is, if $|v| < 2|u|$.

Lemma 5 (Two-square factorization lemma). (See [1].) Given a balanced double square (u, v) , there is a unique primitive string u_1 such that $u = u_1^{e_1}u_2$ and $v = u_1^{e_1}u_2u_1^{e_2}$ where u_2 is a unique, possibly empty, proper prefix of u_1 and e_1, e_2 are unique integers such that $e_1 \geq e_2 \geq 1$. Moreover,

- (a) if $|u_2| = 0$, then $e_1 > e_2$;
- (b) $|u_2| > 0$ if and only if v is primitive;
- (c) if u is primitive, then $|u_2| > 0$;
- (d) if v^2 is a prefix of a string x and there is no other occurrence of u^2 in x , then $|u_2| > 0$.

Given a balanced double square (u, v) , the unique 4-tuple (u_1, u_2, e_1, e_2) yielded by Lemma 5 is referred to as the canonical factorization of the double square (u, v) and is denoted by $(u, v : u_1, u_2, e_1, e_2)$. See the following illustration of Lemma 5 and [1] for a proof.

Lemmas 6 and 7 are considered folklore and are both consequences of the Periodicity Lemma [6], and thus presented here without a proof. However, the interested reader may find their proofs in [1] and a more detailed treatment in [2]. Lemmas 6 and 7 are among the key tools to deal with the canonical factorizations of balanced double squares.

Lemma 6 (Synchronization principle). *The primitive string x occurs exactly p times in $x_2x^px_1$ where p is a non-negative integer and x_1 is a proper prefix of x and x_2 a proper suffix of x .*

Thus, a primitive string is its only conjugate and is not equal to any of its non-trivial rotations. In addition, any rotation or right or left cyclic shift of a primitive string is also primitive.

Lemma 7 (Common factor lemma). *Consider strings x and y where x_1 is a proper prefix of x , x_2 a proper suffix of x , y_1 is a proper prefix of y , and y_2 a proper suffix of y . If for non-negative integers p and q , $x_2x^px_1$ and $y_2y^qy_1$ have a common factor of length $|x|+|y|$, then the primitive root of x and the primitive root of y are conjugates.*

The notion of inversion factor was introduced in [4]: let $(u, v : u_1, u_2, e_1, e_2)$ be a canonical factorization of a balanced double square (u, v) and let \bar{u}_2 denote the suffix of u_1 such that $u_1 = u_2\bar{u}_2$. The inversion factor is defined as $\bar{u}_2u_2u_2\bar{u}_2$. As shown in [4], the inversion factor has only two occurrences in v^2 as indicated in bold below:

$$v^2 = (u_2\bar{u}_2)^{e_1}u_2(u_2\bar{u}_2)^{e_1+e_2}u_2(u_2\bar{u}_2)^{e_2} = (u_2\bar{u}_2)^{e_1-1}u_2\bar{u}_2u_2u_2\bar{u}_2(u_2\bar{u}_2)^{e_1+e_2-2}u_2\bar{u}_2u_2u_2\bar{u}_2(u_2\bar{u}_2)^{e_2-1}$$

Moreover, as shown in [4], for a balanced double square $(u, v : u_1, u_2, e_1, e_2)$

$$0 \leq lcs(u_2\bar{u}_2, \bar{u}_2u_2) + lcp(u_2\bar{u}_2, \bar{u}_2u_2) \leq |u_1| - 2.$$

3. Proof of Lemma 3

Let $u \neq v$, and u^2 and v^2 are both proper prefixes of w^2 . Lemma 3 states that

$$\{ u, v \text{ and } w \text{ have the same primitive root} \} \text{ or } \{ |u|+|v| \leq |w| \}. \tag{S}$$

Without loss of generality, we can assume that $|u| < |v|$.

If $2|v| \leq |w|$, then $|v|+|u| < |w|$ as $|u| < |v|$, and thus (S) holds. Therefore, we can assume that $|w| < 2|v|$; that is, (v, w) is a balanced double square and thus admits a canonical factorization $(v, w : v_1, v_2, p_1, p_2)$ by Lemma 5. We consider the following cases.

1. Case when u and v are not proportional, i.e. $2|u| \leq |v|$. First we prove that $|u| \leq |v_1|$: assuming $|u| > |v_1|$, then u^2 is a prefix of $v = v_1^{p_1}v_2$, and thus u^2 and $v_1^{p_1}v_2$ have a common factor of length $|u|+|v_1|$, and by Lemma 7, $|u| \leq |v_1|$, a contradiction with our assumption. Since we just showed that $|u| \leq |v_1|$ and since $w = vv_1^{p_2}$, it follows that $|w| = |v|+|v_1^{p_2}| \geq |v|+|v_1| \geq |v|+|u|$ and thus (S) holds.
2. Case when u and v are proportional, i.e. $|v| < 2|u|$. Then (u, v) is a balanced double square and thus admits by Lemma 5 a canonical factorization $(u, v : u_1, u_2, e_1, e_2)$.
 - (i) Case when $|u_2| = 0$. Then $e_1 > e_2$, $u = u_1^{e_1}$, and $v = u_1^{e_1+e_2}$. Let us assume that $|w| < |u|+|v| = (2e_1+e_2)|u_1|$. Then w^2 and $u_1^{2e_1+2e_2}$ have a common factor of length $|w|+|u_1|$, and by Lemma 7 the primitive root of w is a conjugate of u_1 , i.e. equals u_1 . Thus, u, v , and w all have the same primitive root, and thus (S) holds.
 - (ii) Case when $|u_2| > 0$. Let $w_{[1]}$ refer to the first occurrence of w and $w_{[2]}$ to the second. First, we have to show that $w_{[1]}$ does not end in the first u_1 of $u_1^{e_1+e_2}$. If it did, then it would contradict Lemma 6 as $w_{[1]}$ and hence $w_{[2]}$ has the primitive u_1 as a prefix as indicated by the following diagram:

Thus, $w_{[1]}$ must end somewhere past the first u_1 of $u_1^{e_1+e_2}$:

As a consequence, $w_{[1]}$ contains the first inversion factor of $u_1^{e_1} u_2 u_1^{e_1+e_2} u_2 u_1^{e_2}$ exactly at a distance of $|u_1^{e_1-1} u_2|$ from the beginning. It follows that $w_{[2]}$ must contain an occurrence of the inversion factor at exactly the same distance from the beginning. If it were the second inversion factor, then the length of w would be exactly $|v|$ as it is the distance between the two occurrences of the inversion factor in w^2 , a contradiction. Thus, it must be an occurrence of the inversion factor past the second one. The first possible start of another occurrence of the inversion factor is the suffix \bar{u}_2 of $u_1^{e_1} u_2 u_1^{e_1+e_2} u_2 u_1^{e_2}$. If $e_1 = e_2$, then it is the case that $w_{[1]} = w_{[2]} = u_1^{e_1-1} (\bar{u}_2 u_2 u_2 \bar{u}_2) u_2^{e_1+e_2-1} u_2$ (see below) and then

$|w| = |u| + |v|$ as $|u| = |u_1^{e_1} u_2|$ and $|v| = |u_1^{e_1+e_2} u_2|$, thus (S) holds. If $e_1 > e_2$, then the occurrence of the inversion factor in $w_{[2]}$ must be at a distance $u_1^{e_1-1} u_2$ from the beginning. By Lemma 6, the prefix $u_1^{e_1-1} u_2$ of $w_{[2]}$ must align with $u_1^{e_2}$ or start in the last u_1 of $u_1^{e_2}$, and so $w_{[1]}$ must have $u_1^{e_1} u_2 u_1^{e_1+e_2} u_2$ as a prefix, again yielding $|w| \geq |u| + |v|$ (see below), thus (S) holds.

4. Conclusion

We presented a generalized version of the Crochemore and Rytter’s lemma on three squares starting at the same position. The generalization relaxes the condition on the shortest among u, v and w being primitive to a more general one, namely, that all three u, v and w do not have the same common primitive root. In particular, $|u| + |v| \leq |w|$ if at least one of u, v or w is primitive. The proof is based on a different approach than the one used by Crochemore and Rytter – an approach using recent insights into the combinatorics of double squares.
