# Process Instances and Labeling

- $a : P$  prefixes each action label in the alphabet of  $P$  with  $a$
- Two instances of a switch process:

$SWITCH = on \rightarrow off \rightarrow SWITCH$

$\parallel TWO\_SWITCH = a : SWITCH \parallel b : SWITCH$

- An array of *instances* of the switch process:

$\parallel SWITCHES(N = 3) = (forall[i : 1..N]s[i] : SWITCH)$

$\parallel SWITCHES(N = 3) = (s[i : 1..N] : SWITCH)$

# Action Relabeling

- Relabeling functions are applied to processes to change the names of action labels. The general form of the relabeling function is:

$/\{newlabel_1/oldlabel_1, \dots, newlabel_n/oldlabel_n\}.$

- Relabeling is used to ensure that composed processes synchronize on particular actions.

$CLIENT = call \rightarrow wait \rightarrow continue \rightarrow CLIENT$

$SERVER = request \rightarrow service \rightarrow reply \rightarrow SERVER$

$\parallel CLIENT\_SERVER = (CLIENT \parallel SERVER) / \{call/request, reply/wait\}$

$CLIENT = call \rightarrow reply \rightarrow continue \rightarrow CLIENT$

$SERVER = call \rightarrow service \rightarrow reply \rightarrow SERVER$

# Process labeling by a set of prefix labels

- $\{a1, \dots, ax\} :: P$  replaces every action label  $n$  in the alphabet of  $P$  with the labels  $a1.n, \dots, ax.n$ . Thus, every transition  $(n \rightarrow X)$  in the definition of  $P$  is replaced with the transitions  $(\{a1.n, \dots, ax.n\} \rightarrow X)$ .

$$(a1.n \rightarrow X \mid a2.n \rightarrow X \mid \dots \mid ax.n \rightarrow X)$$

- Process prefixing is useful for modeling **shared** resources:

$RESOURCE = \text{acquire} \rightarrow \text{release} \rightarrow RESOURCE$

$USER = \text{acquire} \rightarrow \text{use} \rightarrow \text{release} \rightarrow USER$

$\parallel RESOURCE\_SHARE = a : USER \parallel b : USER \parallel \{a, b\} :: RESOURCE$

# Process prefix labels for shared resources

$RESOURCE = \text{acquire} \rightarrow \text{release} \rightarrow RESOURCE$

$USER = \text{acquire} \rightarrow \text{use} \rightarrow \text{release} \rightarrow USER$

$\parallel RESOURCE\_SHARE = a : USER \parallel b : USER \parallel \{a, b\} :: RESOURCE$

**How does the model ensure that the user that acquires the resource is the one to release it?**

$\{a, b\} :: RESOURCE$

**Can this be achieved using relabelling rather than sharing? How?**

# Action relabeling - prefix labels

An alternative formulation of the client server system is described below using qualified or prefixed labels:

```
SERVERv2 = (accept.request  
            ->service->accept.reply->SERVERv2) .  
CLIENTv2 = (call.request  
            ->call.reply->continue->CLIENTv2) .  
  
||CLIENT_SERVERv2 = (CLIENTv2 || SERVERv2)  
                    /{call/accept} .
```

# Action Hiding

- When applied to a process  $P$ , the hiding operator  $\backslash\{a_1 \dots a_x\}$  removes the action names  $a_1 \dots a_x$  from the alphabet of  $P$  and makes these concealed actions “*silent*”. These silent actions are labeled  $\tau$ . Silent actions in different processes are not shared.
- Sometimes it is more convenient to specify the set of labels to be exposed:

When applied to a process  $P$ , the interface operator  $@\{a_1 \dots a_x\}$  *hides* all actions in the alphabet of  $P$  not labeled in the set  $\{a_1 \dots a_x\}$ .

$$USER = (acquire \rightarrow use \rightarrow release \rightarrow USER) \backslash \{use\}$$

$$USER = (acquire \rightarrow use \rightarrow release \rightarrow USER) @ \{acquire, release\}$$

- The above  $\Longleftrightarrow$  follows from the standard procedure of removing  $\varepsilon$ -moves ( $\lambda/\tau$ -moves) in automata theory. This is **NOT** minimization as the textbook claims!

# Structure Diagrams - Systems as Interacting Processes

Process P with  
alphabet  $\{a,b\}$ .

Parallel Composition  
 $(P||Q) / \{m/a, m/b, c/d\}$

Composite process  
 $||S = (P||Q) @ \{x,y\}$

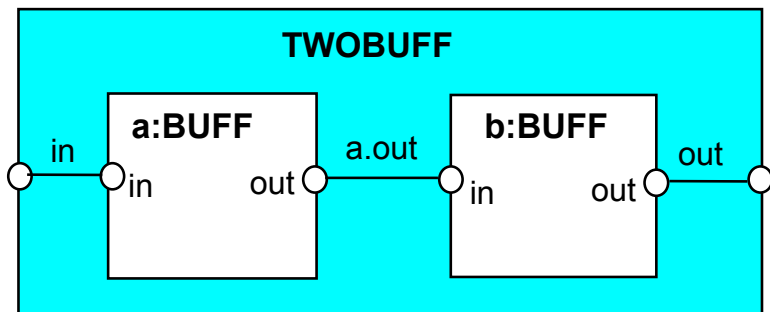

# Structure Diagrams

- We use structure diagrams to capture the structure of a model expressed by the static combinators: *parallel composition*, *relabeling* and *hiding*.

$rangeT = 0..3$

$BUFF = (in[i : T] \rightarrow out[i] \rightarrow BUFF)$

$\parallel TWOBUFF = ((a : BUFF \parallel b : BUFF) / \{a.out / b.in\}) @ \{in, out\}$

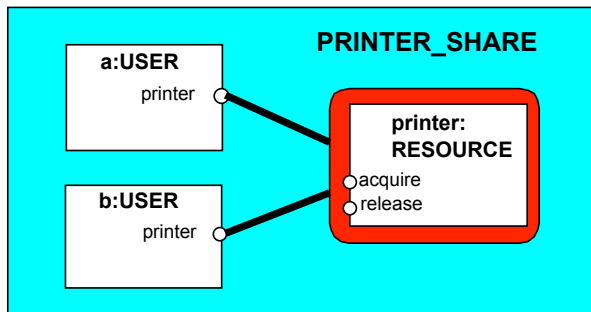

## Structure diagram for **CLIENT\_SERVER**

## Structure diagram for **CLIENT\_SERVERv2**

# Structure Diagrams - Resource Sharing

```
RESOURCE = (acquire->release->RESOURCE) .  
USER =    (printer.acquire->use  
          ->printer.release->USER)\{use} .
```

```
|| PRINTER_SHARE  
= (a:USER || b:USER || {a,b} :: printer:RESOURCE) .
```

```
{a, b} :: printer : RESOURCE =  
(a.printer.acquire → a.printer.release → RESOURCE  
 | b.printer.acquire → b.printer.release → RESOURCE)
```
